APPENDIX B

DISTRESS IDENTIFICATION GUIDE

B-1. User instructions.

- a. Types of distress found in jointed concrete and asphalt-surfaced pavements are listed alphabetically in this appendix. Each listing includes the name of the distress, its description, a narrative and photographic description of its severity levels, and its standard measurement or count criteria. Nineteen distress types have been identified for each of the asphalt and jointed concrete-surfaced pavements; however, only some of these distress types will be encountered frequently during the inspection. Common distress types for asphalt surfaced pavements include alligator cracking, block cracking, bumps, joint reflection cracking, longitudinal and transverse cracking, patching, potholes, rutting, and weathering. Common distress types for jointed concrete pavements include corner break, divided slab, joint seal damage, linear cracking, patching (more than 5 square feet), scaling, shrinkage cracks, corner spalling, and joint spalling. The rest of the distress types included in this appendix may not be encountered as frequently, except in specific geographic locations. For example, durability ("D") cracking in concrete pavements may be encountered frequently in pavements subjected to a high number of freeze-thaw cycles.
- b. It is important that the pavement inspector be thoroughly familiar with all common distress types and their levels of severity. When determining the PCI for a pavement, section, it is imperative that the inspector follow the definitions and criteria described in this manual and appendix. The inspector should study this appendix before an inspection and carry a copy for reference during the inspection.

B-2. Distress in asphalt pavements

- a. During the field condition surveys and validation of the PCI, several questions were commonly asked regarding the identification and measurement of some of the distresses. The answers to these questions are included under the section titled "How to Measure" for each distress. For convenience, however, items that are frequently referenced are listed below:
- (1) If alligator cracking and rutting occur in the same area, each is recorded separately at its respective severity level.

- (2) If bleeding is counted, polished aggregate is not counted in the same area.
- (3) Bumps and sags are measured in units of linear feet.
- (4) If a crack occurs at the ridge or edge of a bump, the crack and bump are recorded separately.
- (5) If any distress (including cracking and potholes) is found in a patched area, is it not recorded; its effect on the patch, however, is considered in determining the severity level of the patch.
- (6) A significant amount of polished aggregate should be present before it is counted.
- (7) Potholes are measured by the number of holes having a certain diameter, not in units of square feet.
- b. The above is not intended to be a complete list. To properly measure each distress type, the inspector must be familiar with its individual measurement criteria.
- c. Nineteen distress types for asphalt-surfaced pavement are listed alphabetically following paragraph B-

B-3. Distress in jointed concrete pavements

- a. Nineteen distress types for jointed concrete pavements are listed alphabetically following the asphalt distress types. Distress definitions apply to both plain and reinforced jointed concrete pavements, with the exception of linear cracking distress, which is defined separately for plain and reinforced jointed concrete.
- b. During the field condition surveys and validation of the PCI, several questions were often asked regarding the identification and counting method of some of the distresses. The answers to these questions are included under the section titled "How to Count" for each distress. For convenience, however, items that are frequently referenced are listed below:
- (1) Faulting is counted only at joints. Faulting associated with cracks is not counted separately

since faulting is incorporated into the severity level definitions of cracks. Crack definitions are also used in defining corner breaks and divided slabs.

- (2) Joint seal damage is not counted on a slabby-slab basis. Instead, a severity level is assigned based on the overall condition of the joint seal in the area.
- (3) Cracks in reinforced concrete slabs that are less than Y inch wide are counted as shrinkage cracks. Shrinkage cracks should not be used to determine if the slab is broken into four or more pieces.
- (4) If the original distress of a patch is more severe than the patch, the original distress is the distress type recorded.
- (5) Low-severity scaling (i.e., crazing) should only be counted if there is evidence that future scaling is likely to occur.
- c. The above is not intended to be a complete list. To properly measure each distress type, the inspector must be familiar with its individual criteria.
- d. The severity level of blow-up and railroad distress in jointed concrete pavements is rated according to the distress effect in ride quality (para B-4).

B-4. Ride quality

Severity Levels:

- a. Ride quality must be evaluated in order to establish a severity level for the following distress types:
 - (1) Bumps.
 - (2) Corrugation.
 - (3) Railroad crossings.

- (4) Shoving.
- (5) Swells.
- b. To determine the effects these distresses have on ride quality, the inspector should use the following severity-level definitions of ride quality:
- (1) *L* (*low*). Vehicle vibrations (e.g., from corrugation) are noticeable, but no reduction in speed is necessary for comfort or safety, and/or individual bumps or settlements cause the vehicle to bounce slightly, but create little discomfort.
- (2) *M* (*medium*). Vehicle vibrations are significant and some reduction in speed is necessary for safety and comfort, and/or individual bumps or settlements cause the vehicle to bounce significantly, creating some discomfort.
- (3) *H* (high). Vehicle vibrations are so excessive that speed must be reduced considerably for safety and comfort, and/or individual bumps or settlements cause the vehicle to bounce excessively, creating substantial discomfort, and/or a safety hazard, and/or high potential vehicle damage.
- c. Ride quality is determined by riding in a standard-size automobile over the pavement section at the posted speed limit. Pavement sections near stop signs should be rated at the normal deceleration speed used when approaching the sign.

ALPHABETICAL LISTING OF DISTRESS TYPES-ASPHALT-SURFACED PAVEMENT

Name of Distress: Alligator Cracking.

Description: Alligator or fatigue

Alligator or fatigue cracking is a series of interconnecting cracks caused by fatigue failure of the asphalt concrete surface under repeated traffic loading. Cracking begins at the bottom of the asphalt surface (or stabilized base) where tensil stress and strain are highest under a wheel load. The cracks propagate to the surface initially as a series of parallel longitudinal cracks. After repeated traffic loading, the cracks connect, forming many-sided, sharp-angled pieces that develop a pattern resembling chicken wire or the skin of an alligator. The pieces are less than 2 feet on the longest side.

Alligator cracking occurs only in areas subjected to repeated traffic loading, such as wheel paths. Therefore, it would not occur over an entire area unless the entire area were subjected to traffic loading. (Pattern-type cracking which occurs over an entire area that is not subjected to loading is called block cracking, which is not a load associated distress.)

Alligator cracking is considered a major structural distress and is usually accompanied by rutting.

L-Fine, longitudinal hairline cracks running parallel to each other with none or only a few interconnecting cracks. The cracks are not spalled * (figs B-1 and B-2).

^{*}Crack spalling is a breakdown of the material along the sides of the crack.

Figure B-1. Low-severity alligator cracking.

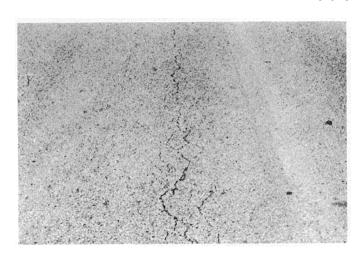

Figure B-2. Low-severity alligator cracking.

M-Further development of light alligator cracks into a pattern or network of cracks that may be lightly spalled (figs B-3, B-4, and B-5).

Figure B-3. Medium-severity alligator cracking

Figure B-4. Medium-severity alligator cracking.

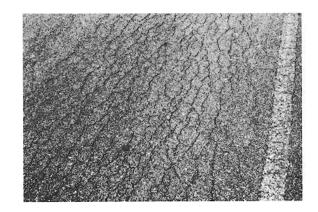

Figure B-5. Medium-severity alligator cracking.

H-Network or pattern cracking has progressed so that the pieces are well defined and spalled at the edges. Some of the pieces may rock under traffic (fig B-6 and B-7).

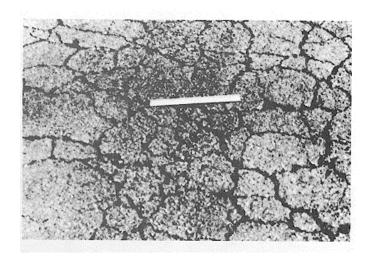

Figure B-6. High-severity alligator cracking.

Figure B-7. High-severity alligator cracking.

Alligator cracking is measured in square feet of surface area. The major difficulty in measuring this type of distress is that two or three levels of severity often exist within one distressed area. If these portions can be easily distinguished from each other, they should be measured and recorded separately. However, if the different levels of Severity cannot be divided easily, the entire area should be rated at the highest severity level present.

Name of Distress: Description:

Bleeding

Bleeding is a film of bituminous material on the pavement surface which a creates shiny, glass like, reflecting surface that usually becomes quite sticky. Bleeding is caused by excessive asphalt cement or tars in the mix, excess application of a bituminous sealant, and/or low air void content. It occurs when asphalt fills the voids of the mix during hot weather and then expands onto the pavement surface. Since the bleeding process is not reversible during cold weather, asphalt or tar will accumulate on the surface.

Severity Levels:

L-Bleeding has only occurred to a very slight degree and it is noticeable only during a few days of the year. Asphalt does not stick to shoes or vehicles (fig B-8).

M-Bleeding has occurred to the extent that asphalt sticks to shoes and vehicles during only a few weeks of the year (fig B-9).

Figure B-8. Low-severity bleeding.

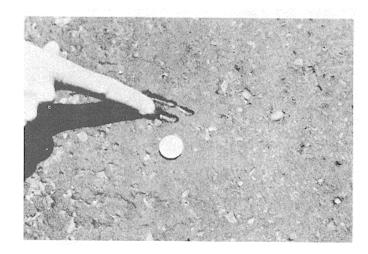

Figure B-9. Medium-severity bleeding.

H-Bleeding has occurred extensively and considerable asphalt sticks to shoes and vehicles during at least several weeks of the year (fig B-10).

Figure B-10. High-severity bleeding.

How to Measure:

Bleeding is measured in square feet of surface area. If bleeding is counted, polished aggregate should not be counted.

Name of Distress: Description:

Block Cracking

Block cracks are interconnected cracks that divide the pavement into approximately rectangular pieces. The blocks may range in size from approximately 1 by 1 foot to 10 by 10 feet. Block cracking is caused mainly by shrinkage of the asphalt concrete and daily temperature cycling (which results in daily stress/strain cycling). It is not load-associated. Block cracking usually indicates that the asphalt has hardened significantly. Block cracking normally occurs over a large proportion of pavement area, but sometimes will occur only in nontraffic areas. This type of distress differs from alligator cracking in that alligator cracks form smaller, many-sided pieces with sharp angles. Also, unlike block cracks, alligator cracks are caused by repeated traffic loadings, and are therefore found only in traffic areas (i.e., wheel paths).

Severity Levels:

L-Blocks are defined by low*-severity cracks (fig B-11).

^{*}See definition of longitudinal and transverse cracking.

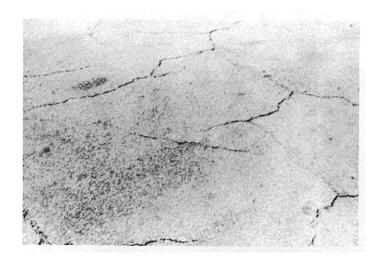

Figure B-11. Low-severity block cracking.

M-Blocks are defined by medium*-severity cracks (fig B-12 and B-13).

Figure B-12. Medium-severity block cracking.

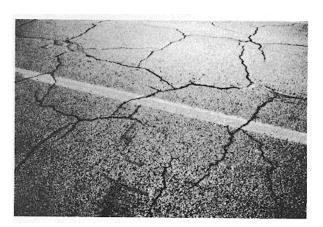

Figure B-13. Medium-severity block cracking.

H-Blocks are defined by high*-severity cracks (fig B-14).

Figure B-14. High-severity block cracking.

^{*}See definition of longitudinal and transverse cracking.

Name of Distress: Description:

Severity Levels:

Block cracking is measured in square feet of surface area. It usually occurs at one severity level in a given pattern section; however, any areas of the pavement section having a distinctly different level of severity should be measured and recorded separately.

Bumps and Sags.

Bumps are small, localized, upward displacements of the pavement surface. They are different form shoves in that shoves are caused by unstable pavement. Bumps, on the other hand, can be caused by several factors, including-

- 1. Buckling or bulging of underlying Portland cement concrete (PCC) slabs in asphalt concrete (AC) overlay over PCC pavement.
- 2. Frost heave (ice, lens growth).
- 3. Infiltration and buildup of material in a crack in combination with traffic loading (sometimes called tenting).

Sags are small, abrupt, downward displacements of the pavement surface.

Distortion and displacement which occurs over large areas of the pavement surface, causing large and/or long dips in the pavement is called swelling.

L-Bump or sag causes low-severity ride quality (fig B-15).

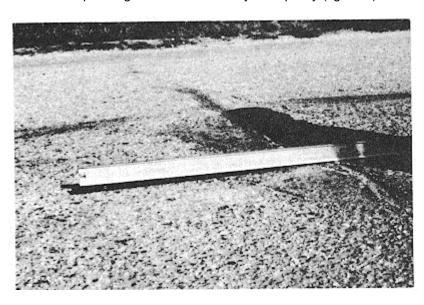

Figure B-15. Low-severity bumps and sags.

M-Bump or sag causes medium-severity ride quality (figs B-16, B-17, and B-18).

Figure B-16. Medium-severity bumps and sags.

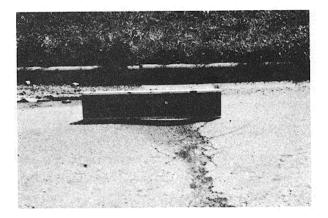

Figure B-17. Medium-severity bumps and sags.

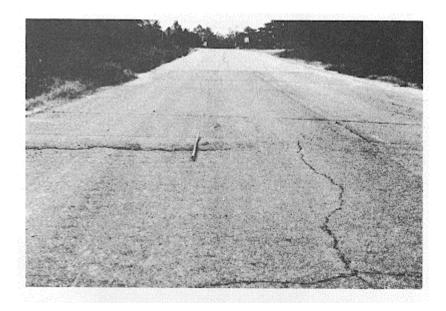

Figure B-18. Medium-severity bumps and sags.

H-Bump or sag cause high-severity ride quality (fig B-19).

How to Measure:

Name of Distress: Description:

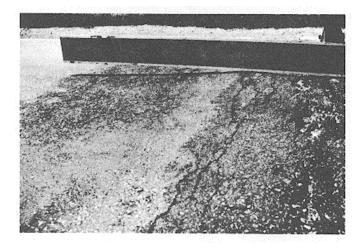

Severity Levels.

Bumps or sags are measured in linear feet. If bumps appear in a pattern perpendicular to traffic flow and are spaced at less than 10 feet, the distress is called corrugation. If the bump occurs in combination with a crack, the crack is also recorded.

Corrugation.

Corrugation (also known as washboarding) is a series of closely spaced ridges and valleys (ripples) occurring at fairly regular intervals-usually less than 10 feet along the pavement. The ridges are perpendicular to the traffic direction. This type of distress is usually caused by traffic action combined with an unstable pavement surface or base. If bumps occur in a series of less than 10 feet, due to any cause, the distress is considered corrugation.

L-Corrugation produces low-severity ride quality (fig B-20).

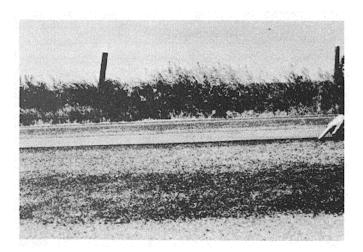

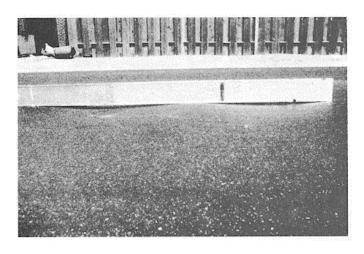

Figure B-20. Low-severity corrugation.

M-Corrugation produces medium-severity ride quality (figs B-21 and B-22).

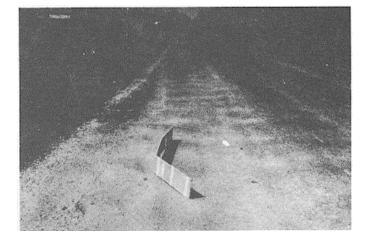

Figure B-21. Medium-severity corrugation.

Figure B-22. Medium-severity corrugation.

H-Corrugation produces high-severity ride quality (fig B-23).

How to Measure: Name of Distress: Corrugation is measured in square feet of surface area.

Depression.

Description:

Localized pavement surface areas with elevations slightly lower than those of the surrounding pavement are called depressions. In many instances, light depressions are not noticeable until after a rain, when ponding water creates "birdbath" areas; on dry pavement, depressions can be spotted by looking for stains caused by ponding water. Depressions are created by settlement of the foundation soil or are a result of improper construction. Depressions cause some roughness, and when filled with water of sufficient depth, can cause hydroplaning. Sags, unlike depressions, are abrupt drops in elevations.

Severity Levels:

Maximum depth of depression:

L-1/2 to 1 inch. M-1 to 2 inches. H-more than 2 inches.

See figures B-24 through B-26.

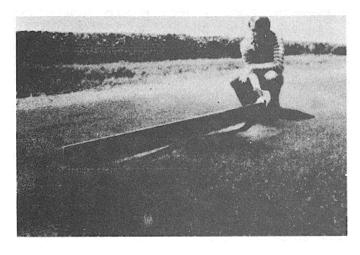

Figure B-23. High-severity corrugation.

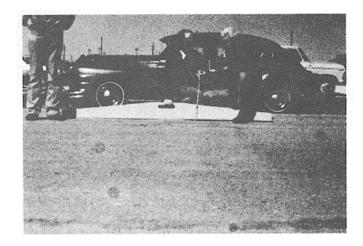

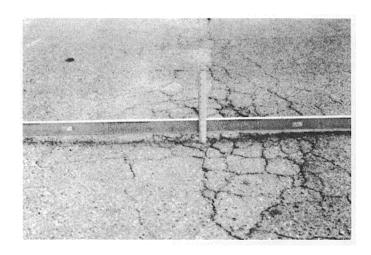

Figure B-24. Low-severity depression.

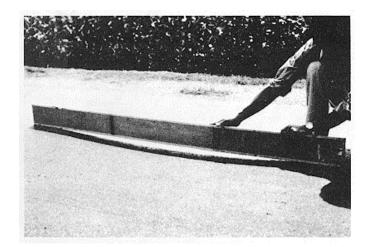

Figure B-25. Medium-severity depression.

Figure B-26. High-severity depression.

How to Measure: Name of Distress: Description: Depressions are measured in square feet of surface area.

Edge Cracking.

Edge cracks are parallel to and usually within 1 to 2 feet of the outer edge of the pavement. This distress is accelerated by traffic loading and can be caused by frost-weakened base or subgrade near the edge of the pavement. The area between the crack and pavement edge is classified as raveled if it breaks up

(sometimes to the extent that pieces are removed).

Severity Levels:

L-Low or medium cracking with no breakup or raveling (fig B-27). M-Medium cracks with some breakup and raveling (fig B-28).

Figure B-27. Low-severity edge cracking.

Figure B-28. Medium-severity edge cracking.

H-Considerable breakup or raveling along the edge (figs B-29 and B-30).

Figure B-29. High-severity edge cracking.

Figure B-30. High-severity edge cracking.

How to Measure: Name of Distress: Description:

Edge cracking is measured in linear feet.

Joint Reflection Cracking (from Longitudinal and Transverse PCC Slabs).

This distress occurs only on asphalt-surfaced pavements which have been laid over a PCC slab. It does not include reflection cracks from any other type of base (i.e., cement- or lime-stabilized); such cracks are listed as longitudinal cracks and transverse cracks. Joint reflection cracks are mainly caused by the thermal- or moisture-induced movement of the PCC slab beneath the AC surface. This distress is not load-related; however, traffic loading may cause a breakdown of the AC surface near the crack. If the pavement is fragmented along a crack, the crack is said to be spalled. A knowledge of slab dimensions beneath the AC surface will help to identify these distresses.

L-One of the following conditions exists (fig B-31):

Figure B-31. Low-severity joint reflection cracking.

- Nonfilled crack width is less than X inch, or
- Filled crack of any width (filler in satisfactory condition). M-One of the following conditions exists (fig B-32):

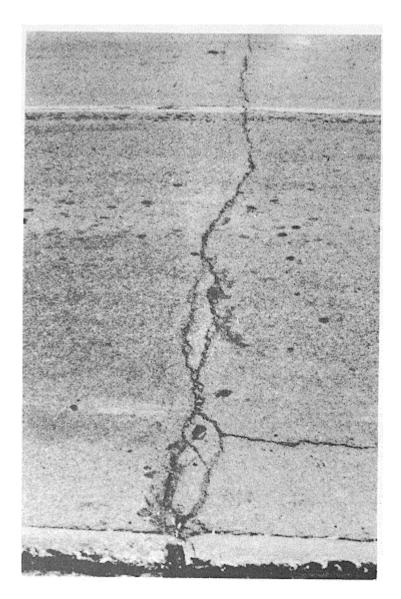

Figure B-32. Medium-severity joint reflection cracking.

- 1. Nonfilled crack width is % to 3 inches.
- Nonfilled crack of any width up to 3 inches surrounded by light random cracking (fig B-32).
- 3. Filled crack of any width surrounded by light random cracking.
- H-One of the following conditions exists (fig B-33):

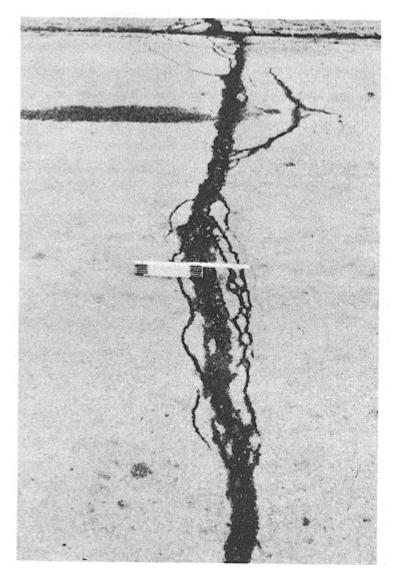

Figure B-33. High-severity joint reflection cracking.

- 1. Any crack, filled or nonfilled, surrounded by medium- or high-severity random cracking.
- 2. Nonfilled cracks over 3 inches.
- 3. A crack of any width where a few inches of pavement around a crack is severely broken. (Crack is severely broken.)

Joint reflection cracking is measured in linear feet. The length and severity level of each crack should be recorded separately. For example, a crack that is 50 feet long may have 10 feet of high severity; these would all be recorded separately. If a bump occurs at the reflection crack, it is also recorded.

Lane/Shoulder Drop Off.

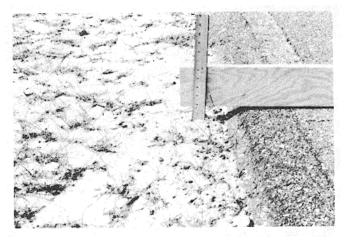

Lane/shoulder drop off is a difference in elevation between the pavement edge and the shoulder. This distress is caused by shoulder erosion, shoulder settlement, or by building up the roadway without adjusting the shoulder level.

L-The difference in elevation between the pavement edge and shoulder is 1 to 2 inches (fig B-34).

How to Measure:

Name of Distress: Description:

M-The difference in elevation is over 2 to 4 inches (fig B-35).

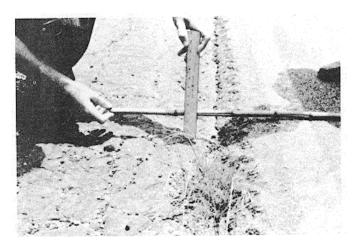

Figure B-35. Medium-severity lane/shoulder drop off.

H-The difference in elevation is greater than 4 inches (figs B-36 and B-37).

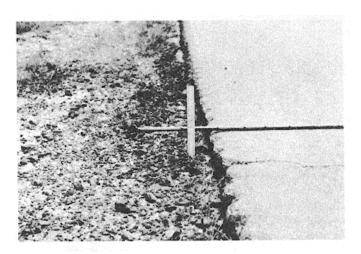

Figure B-36. High-severity lane/shoulder drop off.

Figure B-37. High-severity lane/shoulder drop off

How to Measure: Name of Distress: Description: Lane/shoulder drop off is measured in linear feet.

Longitudinal and Transverse Cracking (Non-PCC Slab Joint Reflective).

Longitudinal cracks are parallel to the pavement's centerline or laydown direction. They may be caused by-

- 1. A poorly constructed paving lane joint.
- 2. Shrinkage of the AC surface due to low temperatures or hardening of the asphalt and/or daily temperature cycling.
- 3. A reflective crack caused by cracking beneath the surface course, including cracks in PCC slabs (but not PCC joints).

Transverse cracks extend across the pavement at approximately right angles to the pavement centerline or direction of laydown. These may be caused by conditions 2 and 3 above. These types of cracks are not usually load-associated.

L-One of the following conditions exists (see fig B-38):

- 1. Nonfilled crack width is less than % inches, or
- 2. Filled crack of any width (filler in satisfactory condition).

M-One of the following conditions exists (figs B-39 and B-40):

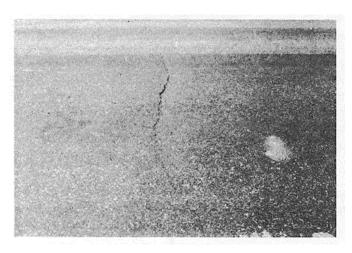

Figure B-38. Low-severity longitudinal and transverse cracking.

Figure B-39. Medium-severity longitudinal and transverse cracking.

- 1. Nonfilled crack width is X8 to 3 inches.
- Nonfilled crack of any width up to 3 inches surrounded by light and random cracking.
- 3. Filled crack of any width surrounded by light random cracking.
- H-One of the following conditions exists (fig B-41):

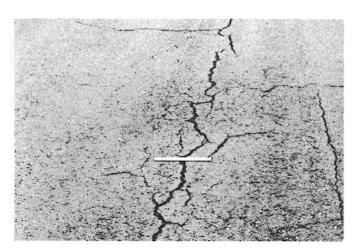

Figure B-40. Medium-severity longitudinal and transverse cracking (A4 inch crack surrounded by light random cracks).

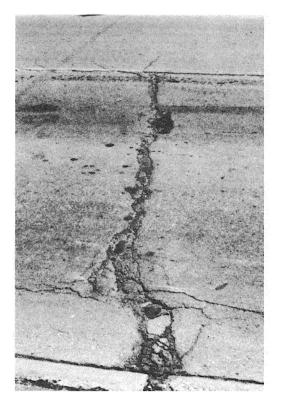

Figure B-41. High-severity longitudinal and transverse cracking.

- 1. Any crack filled or nonfilled surrounded by medium- or high-severity random cracking.
- 2. Nonfilled crack over 3 inches.
- 3. A crack of any width where a few inches of pavement around the crack is severely broken.

Name of Distress: Description:

Severity Levels:

Longitudinal and transverse cracks are measured in linear feet. The length and severity of each crack should be recorded after identification. If the crack does not have the same severity level along its entire length, each portion of the crack having a different severity level should be recorded separately. If a bump or sag occurs at the crack, it is also recorded.

Patching and Utility Cut Patching.

- A patch is an area of pavement which has been replaced with new material to repair the existing pavement. A patch is considered a defect no matter how well it is performing. (A patched area or adjacent area usually does not perform as well as an original pavement section.) Generally, some roughness is associated with this distress.
- L-Patch is in good condition and satisfactory. Ride quality is rated as low-severity or better (figs B-42, B-43, and B-44).
- M-Patch is moderately deteriorated and/or ride quality is rated as medium-severity (fig B-45).

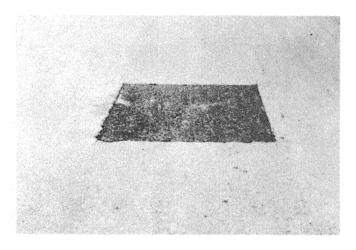

Figure B-42. Low-severity patching and utility cut patching.

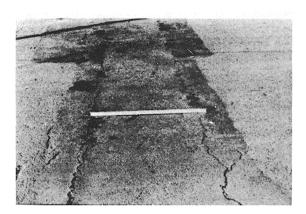

Figure B-44. Low-severity patching and utility cut patching.

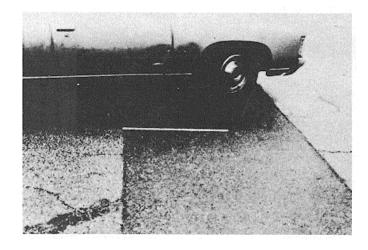

Figure B-43. Low-severity patching and utility cut patching.

Figure B-45. Medium-severity patch.

Name of Distress: Description:

Severity Levels:

H-Patch is badly deteriorated and/or ride quality is rated as high severity. Patch needs replacement soon (fig B-46).

Patching is rated in square feet of surface area. However, if a single patch has areas of differing severity, these areas should be measured and recorded separately. For example, a 25-square-foot patch may have 10 square feet of medium severity and 15 square feet of low severity. These areas would be recorded separately. No other distresses (e.g., shoving or cracking) are recorded within a patch (e.g., even if patch material is shoving or cracking, the area is rated only as a patch).

If a large amount of pavement has been replaced, it should not be recorded as a patch, but considered as new pavement (e.g., replacement of full intersection).

Polished Aggregate.

This distress is caused by repeated traffic applications. When the aggregate in the surface becomes smooth to the touch, adhesion with vehicle tires is considerably reduced. When the portion of aggregate extending above the surface is small, the pavement texture does not significantly contribute to reducing vehicle speed. Polished aggregate should be counted when close examination reveals that the aggregate extending above the asphalt is negligible, and the surface aggregate is smooth to the touch. This type of distress is indicated when the number on a skid resistance test is low or has dropped significantly from previous ratings.

No degrees of severity are defined. However, the degree of polishing should be significant before it is included in the condition survey and rated as a defect (fig B-47).

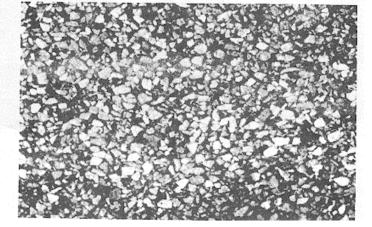

Figure B-46. High-severity patching and utility cut patching.

Figure B-47. Polished aggregate.

How to Count:

Name of Distress: Description:

Polished aggregate is measured in square feet of surface area. If bleeding is counted, polished aggregate should not be counted.

Potholes.

Potholes are small (usually less than 3 feet in diameter), bowl-shaped depressions in the pavement surface. They generally have sharp edges and vertical sides near the top of the hole. Their growth is accelerated by free moisture collection inside the hole. Potholes are produced when traffic abrades small pieces of the pavement surface. The pavement then continues to disintegrate because of poor surface mixtures, weak spots in the base or subgrade, or because it has reached a condition of high-severity alligator cracking. Potholes are generally structurally related distresses and should not be confused with raveling and weathering. Thus, when holes are created by high-severity alligator cracking, they should be identified as potholes, not as weathering.

Severity Levels:

The levels of severity for potholes under 30 inches in diameter are based on both the diameter and the depth of the pothole according to the following table.

Average diameter (inches) Maximum depth of pothole Over 18 to Over 8 to 18 4 to 8 30 1/2 to 1..... Μ L Μ Н >1 to 2 L Н >2 М M

If the pothole is over 30 inches in diameter, the area should be determined in square feet and divided by 5 square feet to find the equivalent number of holes. If the depth is 1 inch or less, they are considered medium severity. If the depth is over 1 inch, they are considered high severity (figs B-48 through B-52).

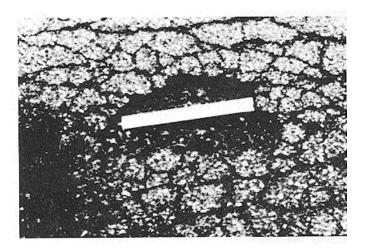

Figure B-48. Low-severity pothole.

Figure B-50. Medium-severity pothole.

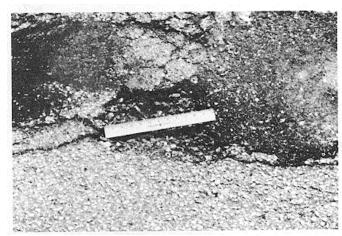

Figure B-49. Low-severity pothole.

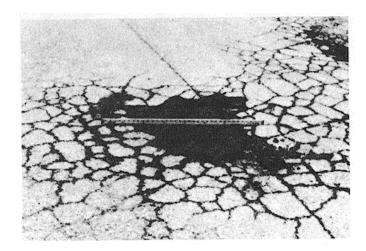

Figure B-51. High-severity pothole.

Potholes are measured by counting the number that are low-, medium-, and highseverity and recording them separately.

Name of Distress:

Railroad Crossing.

Description:

Railroad crossing defects are depressions or bumps around and/or between tracks.

Severity Levels:

L-Railroad crossing causes low-severity ride quality (fig B-53).

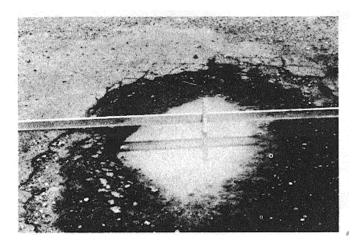

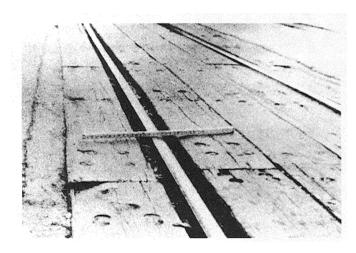

Figure B-52. High-severity pothole.

Figure B-53. Low-severity railroad crossing.

M-Railroad crossing causes medium-severity ride quality (fig B-54). H-Railroad crossing causes high-severity ride quality (fig B-55).

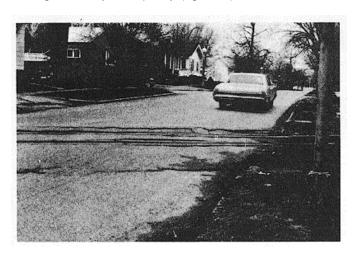

Figure B-54. Medium-severity railroad crossing.

Figure B-55. High-severity railroad crossing.

How to Measure:

The area of the crossing is measured in square feet of surface area. If the crossing does not affect ride quality, it should not be counted. Any large bump created by the tracks should be counted as part of the crossing. Rutting.

Name of Distress: Description:

A rut is a surface depression in the wheel paths. Pavement uplift may occur along the sides of the rut, but in many instances, ruts are noticeable only after a rainfall, when the paths are filled with water. Rutting stems from a permanent deformation in any of the pavement layers or subgrade, usually caused by consolidated or lateral movement of the materials due to traffic loads. Significant rutting can lead to major structural failure of the pavement.

Severity Levels: Mean Rut Depth:

> L-1/4- to 1/2 inches. M--> 1/2 to 1 inches.

H-> 1 inches.

See figures B-56 through B-59.

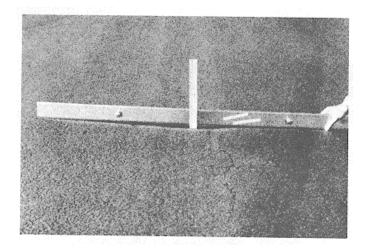

Figure B-56. Low-severity rutting.

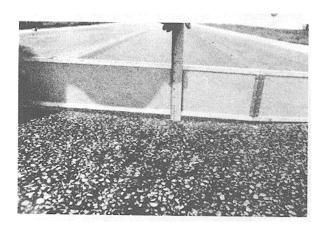

Figure B-58. Medium-severity rutting.

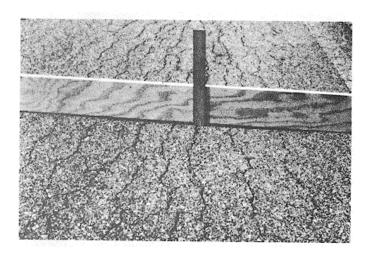

Figure B-57. Low-severity rutting.

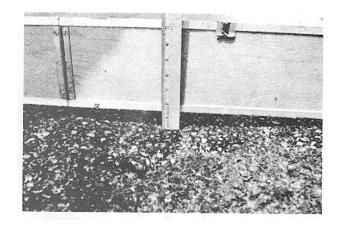

Figure B-59. High-severity rutting.

How to Measure:

Rutting is measured in square feet of surface area, and its severity is determined by the mean depth of the rut (see above). The mean rut depth is calculated by laying a straightedge across the rut, measuring its depth, then using measurements taken along the length of the rut to compute its mean depth in inches.

Name of Distress: Description:

Shoving.

Shoving is a permanent, longitudinal displacement of a localized area of the pavement surface caused by traffic loading. When traffic pushes against the pavement, it produces a short, abrupt wave in the pavement surface. This distress normally occurs only in unstable liquid asphalt mix (cutback or emulsion) pavements.

Shoves also occur where asphalt pavements abut PCC pavements; the PCC pavements increase in length and push the asphalt pavement, causing the shoving.

L-Shove causes low-severity ride quality (fig B-60).

M-Shove causes medium-severity ride quality (fig B-61).

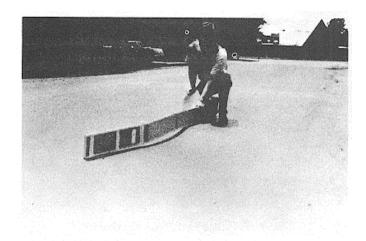

Figure B-60. Low-severity shoving.

Figure B-61. Medium-severity shoving approaching high severity.

How to Measure:

Name of Distress: Description:

Severity Levels:

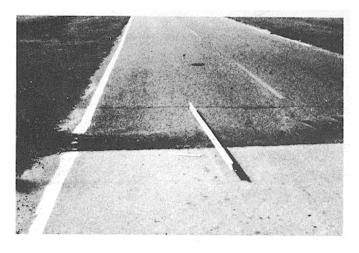

H-Shove causes high-severity ride quality (fig B-62). Shoves are measured in square feet of surface area.

Shoves occurring in patches are considered in rating the patch, not as a separate distress.

Slippage Cracking.

Slippage cracks are crescent or half-moon-shaped cracks having two ends pointing away from the direction of traffic. They are produced when breaking or turning wheels cause the pavement surface to slide or deform. This distress usually occurs when there is a low-strength surface mix or a poor bond between the surface and the next layer of the pavement structure.

L-Average crack width is less than % inch (fig B-63).

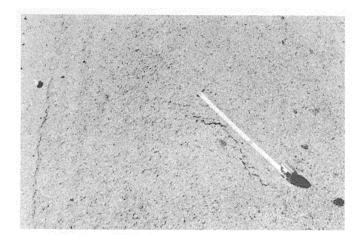

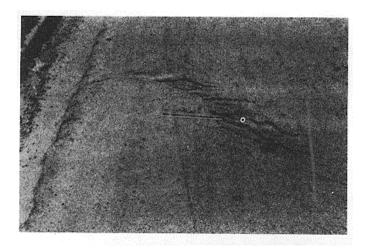

Figure B-63. Low-severity slippage cracking.

M-One of the following conditions exists (fig B-64):

- 1. Average crack width is between X and 1 inches.
- 2. The area around the crack is broken into tight-fitting pieces.

H-One of the following conditions exists (fig B-65):

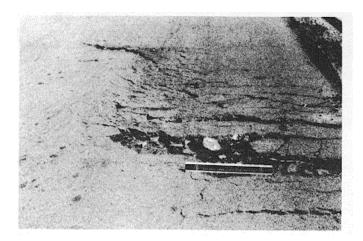

Figure B-64. Medium-severity slippage cracking.

Figure B-65. High-severity slippage cracking.

Name of Distress: Description:

Severity Levels:

1. The average crack width is greater than 11 inches.

2. The area around the crack is broken into easily removed pieces.

The area associated with a given slippage crack is measured in square feet and rated according to the highest level severity in the area.

Swell.

Swell is characterized by an upward bulge in the pavement's surface-a long, gradual wave of more than 10 feet long. Swelling can be accompanied by surface cracking. This distress is usually caused by frost action in the subgrade or by swelling soil.

L-Swell causes low-severity ride quality. Low-severity swells are not always easy to see, but can be detected by driving at the speed limit over the pavement section. An upward acceleration will occur at the swell if it is present. (See fig B-66.) M-Swell causes medium-severity ride quality. (See fig B-66.) H-Swell causes high-severity ride quality. (See fig B-66.)

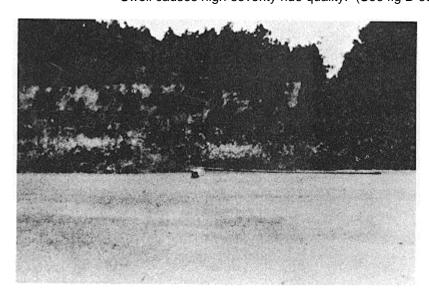

Figure B-66. Example swell; severity level is based on ride quality criteria.

How to Measure: Name of Distress: The surface of the swell is measured in square feet. Weathering and Raveling.

Description:

Severity Levels:

Weathering and raveling are the wearing away of the pavement surface caused by the loss of asphalt or tar binder and dislodged aggregate particles. These distresses indicate that either the asphalt binder has hardened appreciably or that a poor-quality mixture is present. In addition, raveling may be caused by certain types of traffic, e.g., tracked vehicles.

L-Aggregate or binder has started to wear away. In some areas, the surface is starting to pit (figs B-67 and B-68).

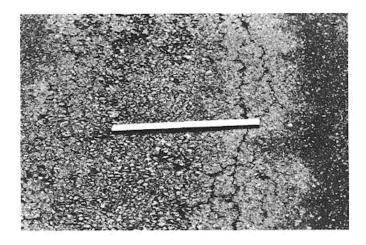

Figure B-67. Low-severity weathering and raveling.

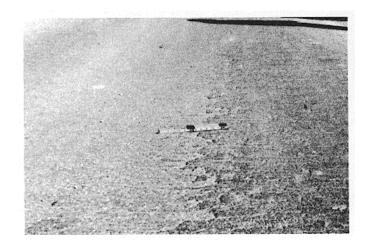

Figure B-68. Low-severity weathering and raveling caused by tracked vehicles.

M-Aggregate and/or binder has worn away. The surface texture is moderately rough and pitted (figs B-69 and B-70).

Figure B-69. Medium-severity weathering and raveling.

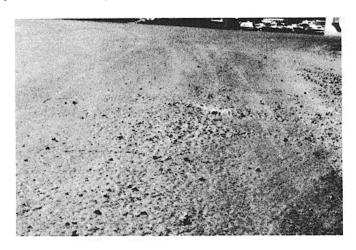

Figure B-70. Medium-severity weathering and raveling.

H-Aggregate and/or binder has been considerably worn away. The surface texture is very rough and severely pitted. The pitted areas are less than 4 inches in diameter and less than 3 inch deep; pitted areas larger than this are counted as potholes (fig B-71).

Weathering and raveling are measured in square feet of surface area.

ALPHABETICAL LISTING OF DISTRESS TYPES-JOINTED CONCRETE PAVEMENTS

Name of Distress: Description:

Blow-up/Buckling.

Blow-ups or buckles occur in hot weather, usually at a transverse crack or joint that is not wide enough to permit slab expansion. The insufficient width is usually caused by infiltration of incompressible materials into the joint space. When expansion cannot relieve enough pressure, a localized upward movement of the slab edges (buckling) or shattering will occur in the vicinity of the joint. Blow-ups can also occur at utility cuts and drainage inlets.

Severity Levels:

L-Buckling or shattering causes low-severity ride quality (fig B-72).

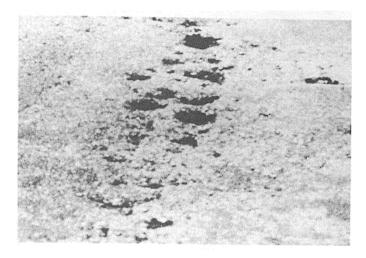

Figure B-71. High-severity weathering and raveling.

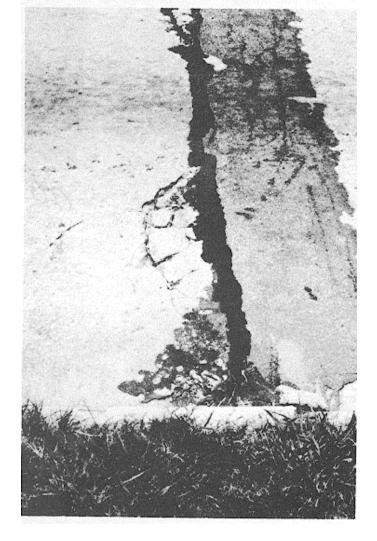

Figure B-72. Low-severity blow-up/buckling.

M-Buckling or shattering causes medium-severity ride quality (figs B-73 and B-74).

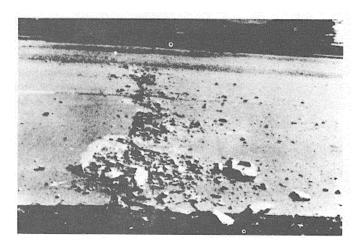

Figure B-74. Medium-severity blow-up/buckling.

Figure B-73. Medium-severity blow-up/buckling.

H-Buckling or shattering causes high-severity ride quality (fig B-75).

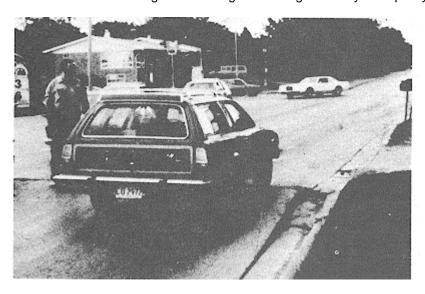

Figure B-75. High-severity blow-up/buckling approach inoperative conditions.

How to Count:

At a crack, a blow-up is counted as being in one slab. However, if the blowup occurs at a joint and affects two slabs, the distress should be recorded as occurring in two slabs. When a blow-up renders the pavement inoperable, it should be repaired immediately.

Corner Break.

Name of Distress:

Description:

A corner break is a crack that intersects the joints at a distance less than or equal to one-half the slab length on both sides, measured from the corner of the slab. For example, a slab with dimensions of 12 by 20 feet that has a crack 5 feet on one side and 12 feet on the other side is not considered a corner break; it is a diagonal crack. However, a crack that intersects 4 feet on one side and 8 feet on the other is considered a corner break. A corner break differs from a corner spall in that the crack extends vertically through the entire slab thickness, while a corner spall intersects the joint at an angle. Load repetition combined with loss of support and curling stresses usually causes corner breaks.

Severity Levels:

L*--Break is defined by a low-severity crack and the area between the break and the joints is not cracked or may be lightly cracked (figs B-76 and B-77).

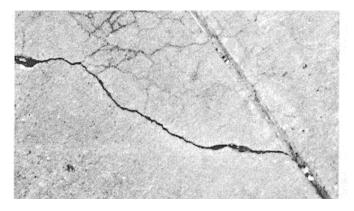

Figure B-76. Low-severity corner break.

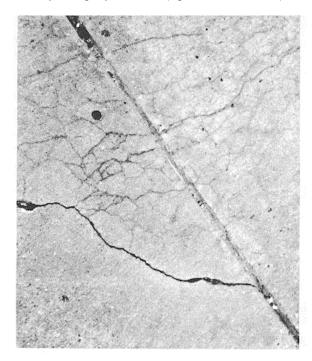

Figure B-77. Low-severity corner break.

- M*-Break is defined by medium-severity crack and/or the area between the break and the joint is mediumly cracked (fig B-78).
- H*--Break is defined by a high-severity crack and/or the area between the break and the joints is highly cracked (fig B-79).

^{*}See linear cracking for a definition of low-, medium, and high-severity cracks.

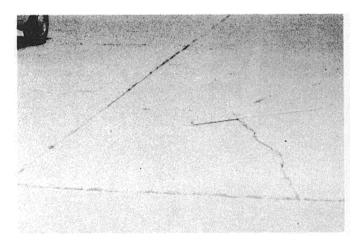

Figure B-78. Medium-severity corner break. Defined by a medium-severity crack.

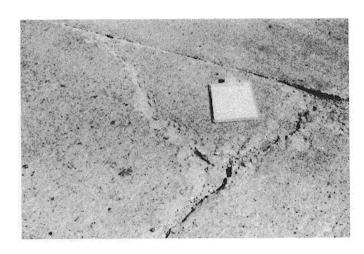

Figure B-79. High-severity corner break.

How to Count:

Distressed slab is recorded as one slab if it::

- 1. Contains a single corner break.
- 2. Contains more than one break of a particular severity.
- 3. Contains two or more breaks of different severities.

For two or more breaks, the highest level of severity should be recorded. For example, a slab containing both low and medium-severity corner breaks should be counted as one slab with a medium corner break.

Divided Slab.

Slab is divided by cracks into four or more pieces due to overloading and/or inadequate support. If all pieces or cracks are contained within a corner break, the distress is categorized as a severe corner break.

Name of Distress: Description:

Severity Levels:

Severity of
majority of
cracks
L
M
Н

Number of pieces in cracked slab

4 to 5	6 to 8	More than 8
L	L	M
M	M	Н
M	Н	Н

See figures B-80 through B-84.

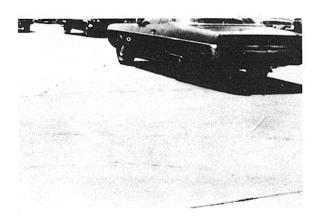

Figure B-80. Low-severity divided slab. Majority of cracks are low severity access than 1/2 inch wide and no faulting).

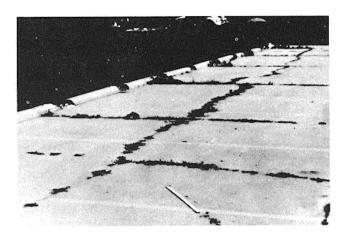

Figure B-81. Medium-severity divided slab.

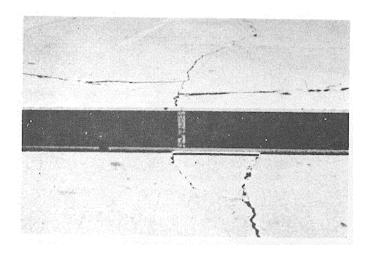

Figure B-82. High-severity divided slab caused by highseverity cracks.

Figure B-83. High-severity divided slab.

Figure B-84. High-severity divided slab.

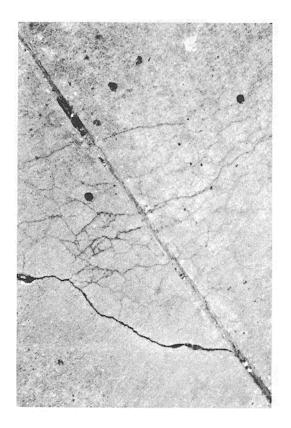

How to Count: Name of Distress: Description:

Severity Levels:

If the slab is medium or high-severity, no other distress is counted. Durability ("D") Cracking.

"D" cracking is caused by freeze-thaw expansion of the large aggregate which, over time, gradually breaks down the concrete. This distress usually appears as a pattern of cracks running parallel and close to a joint or linear crack. Since the concrete becomes saturated near joints and cracks, a dark-colored deposit can usually be found around fine "D" cracks. This type of distress may eventually lead to disintegration of the entire slab.

L-"D" cracks cover less than 15 percent of slab area. Most of the cracks are tight, but a few pieces may have popped out (figs B-85 and B-86).

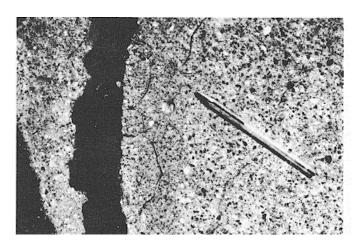

Figure B-86. Low-severity durability cracking.

Figure B-85. Low-severity durability cracking.

M-One of the following conditions exists (fig B-87):

Figure B-87. Medium-severity durability cracking.

- 1. "D" cracks cover less than 15 percent of the area and most of the pieces have popped out or can be easily removed.
- 2. "D" cracks cover more than 15 percent of the area. Most of the cracks are tight, but a few pieces may have popped our or can be easily removed.
- H-"D" cracks cover more than 15 percent of the area and most of the pieces have popped out or can be easily removed (see figs B-88 and B-89).

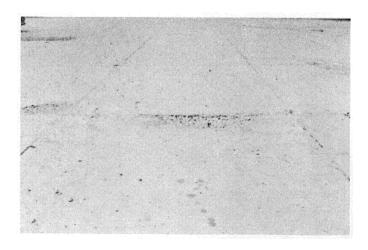

Figure B-88. High-severity durability cracking.

Figure B-89. High-severity durability cracking.

How to Count:

Name of Distress: Description:

Severity Levels:

When the distress is located and rated at one severity, it is counted as one slab. If more than one severity level exists, the slab is counted as having the higher severity distress. For example, if low and medium "D" cracking are on the same slab, the slab is counted as having medium-severity cracking only.

Faulting.

Faulting is the difference in elevation across a joint. Some of the common causes of faulting are:

- 1. Settlement because of soft foundation.
- 2. Pumping or eroding of materiel from under the slab.
- 3. Curling of the slab edges due to temperature and moisture changes.

Severity levels are defined by the difference in elevation across the crack or joint.

Severity level	Difference in elevation
Ĺ	1/8 to 3/8 inch
M	3/8 to 3/4 inch
Н	> 3/4 inch

See figures B-90 through B-93.

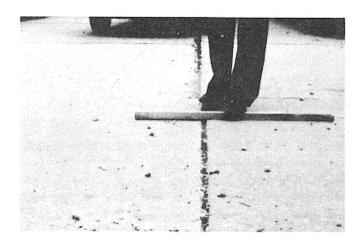

Figure B-90. Low-severity faulting.

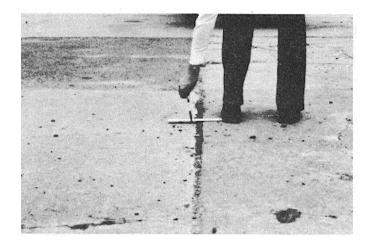

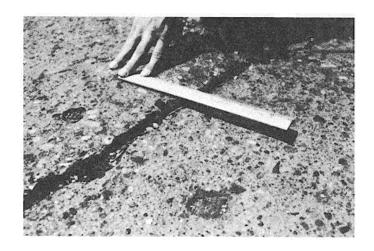

Figure B-91. Medium-severity faulting.

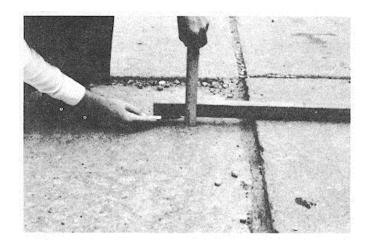

Figure B-92. Medium-severity faulting.

Figure B-93. High-severity faulting.

How to Count:

Name of Distress: Description:

Faulting across a joint is counted as one slab. Only affected slabs are counted. Faults across a crack are not counted as distress, but are considered when defining crack severity.

Joint Seal Damage.

Joint seal damage is any condition which enables soil or rocks to accumulate in the joints or allows significant water infiltration. Accumulation of incompressible materials prevents the slabs from expanding and may result in buckling, shattering, or spalling. A pliable joint filler bonded to the edges of the slabs protects the joints from material accumulation and prevents water from seeping down and softening the foundation supporting the slab.

Typical types of joint seal damage are:

- 1. Stripping of joint sealant.
- 2. Extrusion of joint sealant.
- 3. Weed growth.
- 4. Hardening of the filler (oxidation).
- 5. Loss of bond to the slab edges.
- 6. Lack or absence of sealant in the joint.

L-Joint sealant is in generally good condition throughout the section. Sealant is performing well, with only minor damage (see above) (fig B-94).

M-Joint sealant is in generally fair condition over the entire section, with one more of the above types of damage occurring to a moderate degree. Sealant needs replacement within 2 years (fig B-95).

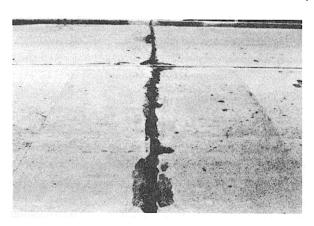

Figure B-94. Low-severity joint seal damage.

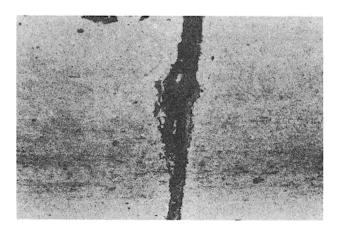

Figure B-95. Medium-severity joint seal damage.

H-Joint sealant is in generally poor condition over the entire section, with one or more of the above types of damage occurring to a severe degree. Sealant needs immediate replacement (figs B-96 and B-97).

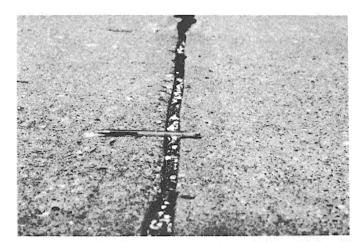

Figure B-96. High-severity joint seal damage.

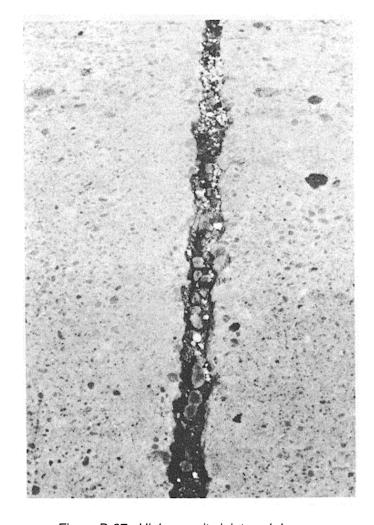

Figure B-97. High-severity joint seal damage.

Joint seal damage is not counted on a slab-by-slab basis, but rated based on the overall condition of the sealant over the entire area.

Lane/Shoulder Drop Off.

Lane/shoulder drop off is the difference between the settlement or erosion of the shoulder and the pavement travel-lane edge. The elevation difference can be a safety hazard; it can also cause increased water infiltration.

L-The difference between the pavement edge and shoulder is 1 to 2 inches (fig B-98).

M-The difference in elevation is 2 to 4 inches (fig B-99).

How to Count:

Name of Distress: Description:

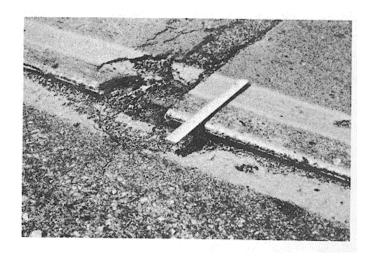

Figure B-98. Low-severity lane/shoulder drop off.

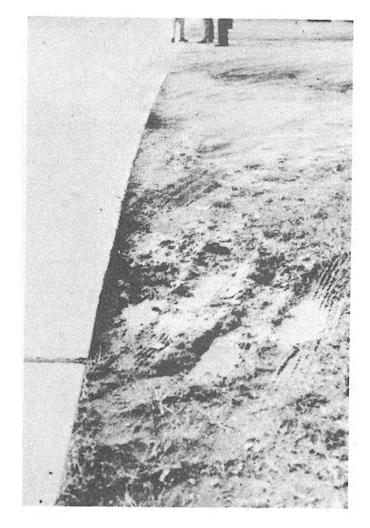

Figure B-99. Medium-severity lane/shoulder drop off
H-The difference in elevation is greater than 4 inches (fig B-100).

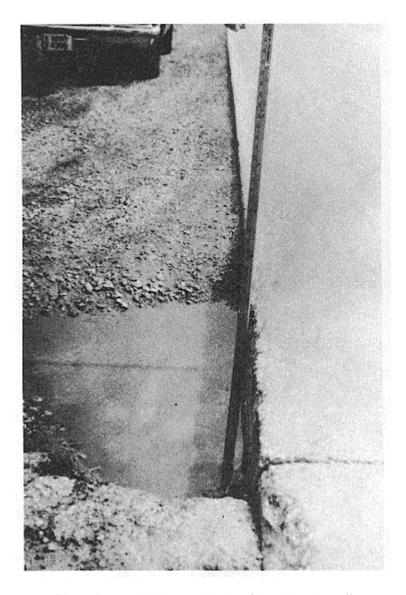

Figure B-100. High-severity lane/shoulder drop off.

How to Count:

Name of Distress:

Description:

The mean lane/shoulder drop off is computed by averaging the maximum and minimum drop along the slab. Each slab exhibiting distress is measured separately and counted as one slab with the appropriate severity level.

Linear Cracking (Longitudinal, Transverse, and Diagonal Cracks).

These cracks, which divide the slab into two or three pieces, are usually caused by a combination of repeated traffic loading, thermal gradient curling, and repeated moisture loading. (Slabs divided into four or more pieces are counted as Divided Slabs.) Low-severity cracks are usually related to warp or friction and are not considered major structural distresses. Medium or high-severity cracks are usually working cracks and are considered major structural distresses (fig B-101 through B-106).

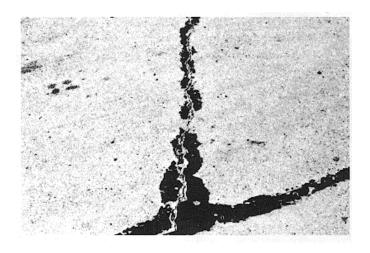

Figure B-101. Low-severity linear cracking in a nonreinforced concrete slab.

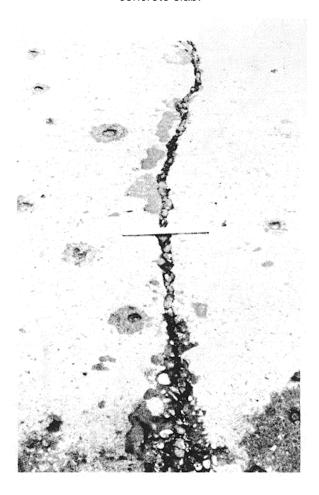

Figure B-103. Medium-severity linear cracking in a reinforced concrete slab.

Figure B-102. Low-severity linear cracking in a nonreinforced concrete slab.

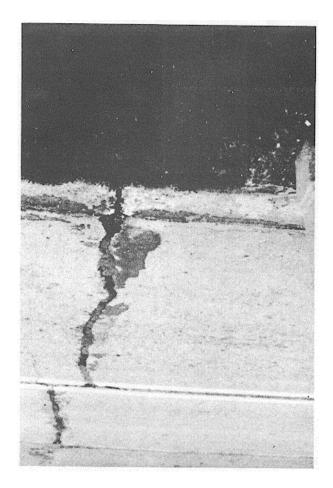

Figure B-104. Medium-severity linear cracking in a reinforced concrete slab.

Figure B-105. High-severity linear cracking in a nonreinforced concrete slab.

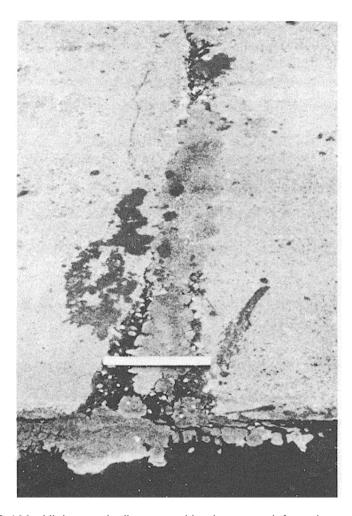

Figure B-106. High-severity linear cracking in a nonreinforced concrete slab.

Hairline cracks that are only a few feet long and do not extend across the entire slab are counted as shrinkage cracks.

Nonreinforced Slabs: L-Nonfilled* cracks less than or equal to Y inch or filled cracks of any width with the filler in satisfactory condition. No faulting exists.

M-One of the following conditions exists:

- 1. Nonfilled crack with a width between Y and 2 inches.
- 2. Nonfilled crack of any width up to 2 inches with faulting of less than \boldsymbol{X} inches.
- 3. Filled crack of any width with faulting less than % inch.

H-One of the following conditions exists:

- 1. Nonfilled crack with a width greater than 2 inches.
- 2. Filled or nonfilled crack of any width with faulting greater than % inch. Reinforced Slabs.

L-Nonfilled cracks with a width of Y8 to 1 inch; filled crack of any width with the filler in satisfactory condition. No faulting exists.

M-One of the following conditions exist:

- 1. Nonfilled cracks with a width between 1 and 3 inches and no faulting.
- 2. Nonfilled crack of any width up to 3 inches with up to v8 inch of faulting.
- 3. Filled crack of any width with faulting less than % inch.

H-One of the following conditions exists:

- 1. Nonfilled crack with width over 3 inches.
- 2. Filled or nonfilled crack of any width with faulting over % inch.

Severity Levels:

^{*}Filed cracks where filler is unsatisfactory are treated as nonfilled.

Name of Distress: Description:

Severity Levels:

Once the severity has been identified, the distress is recorded as one slab. If two medium-severity cracks are within one slab, is counted as having one high-severity crack. Slabs divided into four or more pieces are counted as divided slabs.

In reinforced slabs, cracks with a width less than X inch are counted as shrinkage cracks. Slabs longer than 30 feet are divided into approximately equal length "slabs" having imaginary joints assumed to be in perfect condition.

Patching, Large (more than 5 square feet) and Utility Cuts.

A patch is an area where the original pavement has been removed and replaced by a filler material. A utility cut is a patch that has replaced the original pavement to allow the installation of underground utilities. The severity levels of a utility cut are the same as those for regular patching.

L-Patch is functioning well, with little or no deterioration (figs B-107 and B-108).

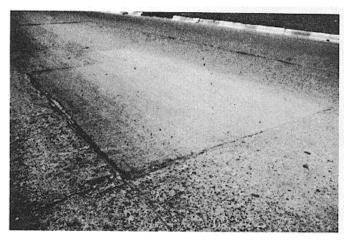

Figure B-107. Low-severity patching, large, and utility cuts.

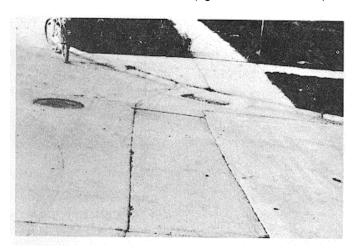

Figure B-108. Low-severity patching, large, and utility cuts.

M-Patch is moderately deteriorated and/or moderate spalling can be seen around the edges. Patch material can be dislodged with considerable effort (figs B-109 through B-111).

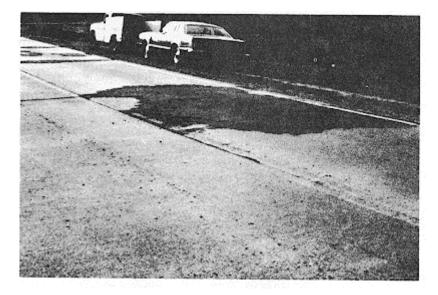

Figure B-109. Medium-severity patching, large.

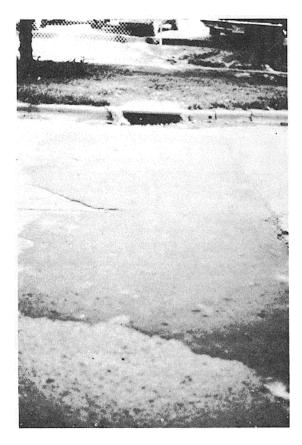

Figure B-111. Medium-severity patching, Utility cuts.

Figure B-110. Medium-severity patching, large.

H-Patch is badly deteriorated. The extent of the deterioration warrants replacement of the patch (fig B-112).

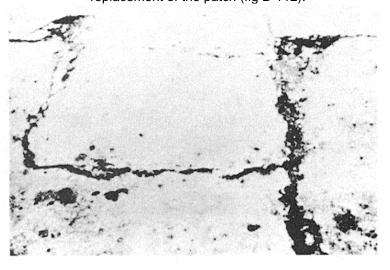

Figure B-112. High-severity patching, large.

How to Count:

If a single slab has one or more patches with the same severity level, it is counted as one slab containing that distress. If a single slab has more than one severity level, it is counted as one slab with the higher severity level.

If the cause of the patch is more severe, only the original distress is counted.

Name of Distress: Description:

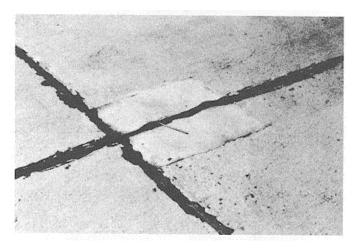

Severity Levels:

Patching, Small (less than 5 square feet).

A patch is an area where the original pavement has been removed and replaced by a filler material.

L-Patch is functioning well with little or no deterioration (fig B-113).

M-Patch is moderately deteriorated. Patch material can be dislodged with considerable effort (fig B-114).

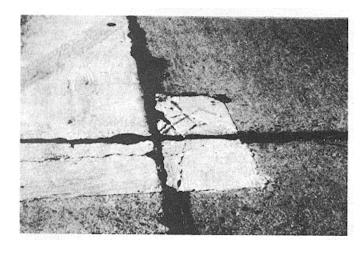

Figure B-114. Medium-severity patching, small.

H-Patch is badly deteriorated. The extent of deterioration warrants replacement of the patch (fig B-115).

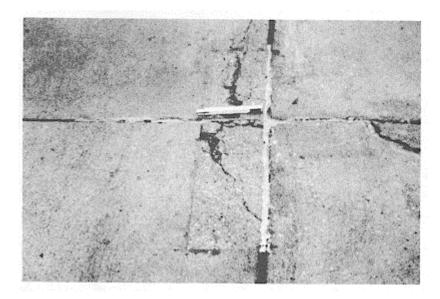

Figure B-115. High-severity patching, small.

How to Count:

If a single slab has one or more patches with the same severity level, it is counted as one slab containing that distress. If a single slab has more than one severity level, it is counted as one slab with the higher severity level.

If the cause of the patch is more severe, only the original distress is counted.

Name of Distress: Description:

Severity Levels:

How to Count: Name of Distress: Description:

Severity Levels:

Polished Aggregate.

This distress is caused by repeated traffic applications. When the aggregate in the surface becomes smooth to the touch, adhesion with vehicle tires is considerably reduced. When the portion of aggregate extending above the surface is small, the pavement texture does not significantly contribute to reducing vehicle speed. Polished aggregate should be counted when close examination reveals that the aggregate extending above the concrete is negligible, and the surface aggregate is smooth to the touch.

This type of distress is indicated when the number on a skid resistance test is low or has dropped significantly from previous ratings.

No degrees of severity are defined. However, the degree of polishing should be significant before it is included in the condition survey and rated as a defect (fig B-116).

A slab with polished aggregate is counted as one slab.

A popout is a small piece of pavement that freeze-thaw action, combined with aggregate expansion, causes to break loose from the surface. Popouts usually range in diameter from approximately 1 to 4 inches and in depth from M to 2 inches.

No degrees of severity are defined for popouts. However, popouts must be extensive before they are counted as a distress. Average popout density must exceed approximately three popouts per square yard over the entire slab area (fig B-117).

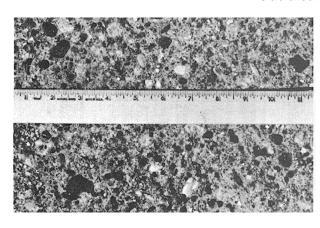

Figure B-116. Polished aggregate.

Figure B-117. Popouts.

How to Count:

Name of Distress: Description:

The density of the distress must be measured. If there is any doubt that the average is greater than three popouts per square yard, at least three random 1-square-yard areas should be checked. When the average is greater than this density, the slab should be counted.

Pumping.

Pumping is the ejection of material from the slab foundation through joints or cracks. This is caused by deflection of the slab by passing loads. As a load moves across the joint between the slabs, water is first forced under the leading slab, and then forced back under the trailing slab.

This erodes and eventually removes soil particles, resulting in progressive loss of pavement support. Pumping can be identified by surface stains and evidence of base or subgrade material on the pavement close to joints or cracks. Pumping near joints is caused by poor joint sealer and indicates loss of support; repeated loading will eventually produce cracks. Pumping can also occur along the slab edge, causing loss of support.

Severity Levels:

No degrees of severity are defined. It is sufficient to indicate the pumping exists (figs B-118 and B-119).

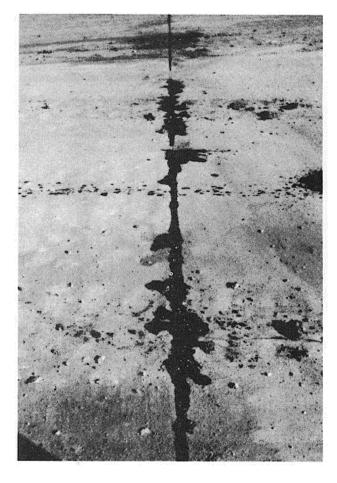

Figure B-118. Pumping.

Figure B-119. Pumping.

How to Count:

Name of Distress: Description:

Severity Levels:

One pumping joint between two slabs is counted as two slabs. However, the remaining joints around the slab are also pumping, one slab is added per additional pumping joint.

Punchout.

This distress is a localized area of the slab that is broken into pieces. The punchout can take many different shapes and forms, but it is usually defined by a crack and a joint, or two closely spaced cracks (usually 5 feet wide). This distress is caused by heavy repeated loads, inadequate slab thickness, loss of foundation support, and/or a localized concrete construction deficiency (e.g., honeycombing).

Majority of	Number of pieces			
cracks severity	2 to 3	4 to 5	>5	
L	L	L	M	
M	L	M	Н	
н	M	н	н	

See figs. B-120 through B-122.

Name of Distress: Description:

Severity Levels:

If a slab contains one or more punchouts, it is counted as containing a punchout at the severity level of the most severe punchout.

Railroad Crossing.

Railroad crossing distress is characterized by depressions or bumps around the tracks.

L-Railroad crossing causes low-severity ride quality (fig B-123).

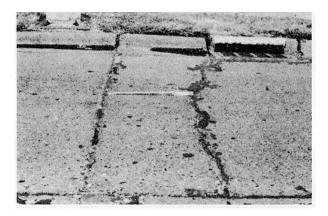

Figure B-120. Low-severity punchout.

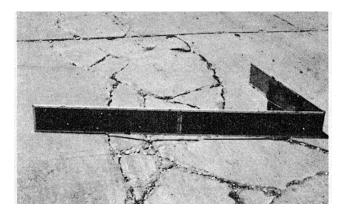

Figure B-122. High-severity punchout.

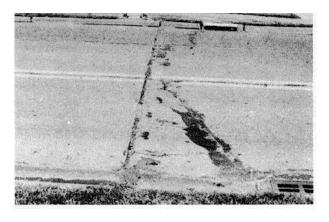

Figure B-121. Medium-severity punchout.

Figure B-123. Low-severity railroad crossings.

M-Railroad crossing causes medium-severity ride quality (fig B-124). H-Railroad crossing causes high-severity ride quality (fig B-125).

Figure B-124. Medium-severity railroad crossings.

Figure B-125. High-severity railroad crossing.

Name of Distress: Description:

Severity Levels:

The number of slabs crossed by the railroad track is counted. Any large pump created by the tracks should be counted as part of the crossing.

Scaling/Map Cracking/Crazing.

Map cracking or crazing refers to a network of shallow, fine, or hairline cracks which extend only through the upper surface of the concrete.

The cracks tend to intersect at angles of 120 degrees. Map cracking or crazing is usually caused by concrete overfinishing, and may lead to surface scaling, which is the breakdown of the slab surface to a depth of approximately Y4 to 3 inch. Scaling may also be caused by deicing salts, improper construction, freeze-thaw cycles, and poor aggregate. The type of scaling defined here is not caused by "D" cracking. If scaling is caused by "D" cracking, it should be counted under that distress only.

L-Crazing or map cracking exists over most of the slab area; the surface is in good condition, with only minor scaling present (fig B-126).

M-Slab is scaled, but less than 15 percent of the slab is affected (fig B-127).

Figure B-126. Low-severity scaling/map cracking/crazing.

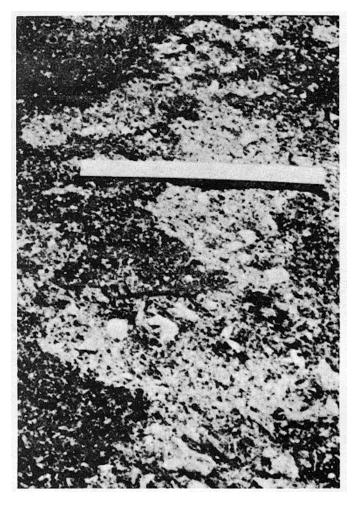

Figure B-127. Medium-severity scaling/map cracking/crazing.

H-Slab is scaled over more than 15 percent of its area (figs B-128 through B-130).

Name of Distress: Description:

Severity Levels:

A scaled slab is counted as one slab. Low-severity crazing should only be counted if the potential for scaling appears to be imminent, or few small pieces have come out.

Shrinkage Cracks.

Shrinkage cracks are hairline cracks that are usually only a few feet long and do not extend across the entire slab. They are formed during the setting and curing of the concrete and usually do not extend through the depth of the slab.

No degrees of severity are defined. It is enough to indicate that shrinkage cracks are present (fig B-131).

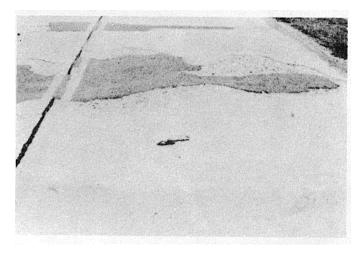

Figure B-128. High-severity scaling/map cracking/crazing.

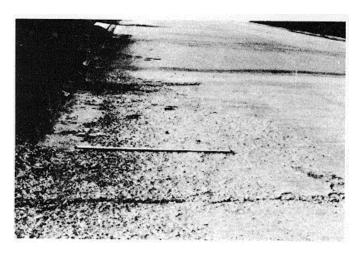

Figure B-130. High-severity scaling/map cracking/crazing.

Figure B-129. High-severity scaling/map cracking/crazing.

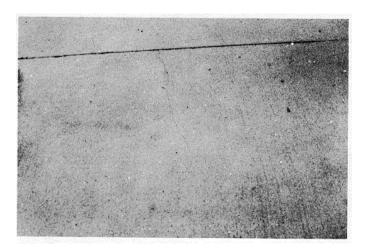

Figure B-131. Shrinkage cracks.

How to Count:

Name of Distress: Description:

If one or more shrinkage cracks exist on one particular slab, the slab is counted as one slab with shrinkage cracks.

Spalling, Corner.

Corner spalling is the breakdown of the slab within approximately 2 feet of the corner. A corner spall differs from a corner break in that the spall usually angles downward to intersect the joint, while a break extends vertically through the slab corner. Spalls less than 5 inches from the crack to the corner on both sides should not be counted.

Severity Levels:

	Dimensions of sides of spall		
Depth of spall	5 x 5 inches to	12 x 12 inches	
12 x 12 inches			
<1 inch	. L	L	
1 to 2 inches	. L	M	
>2 inches	. M	Н	

Corner spalling having an area of less than 10 square inches is not counted (figs B-132 through B-135).

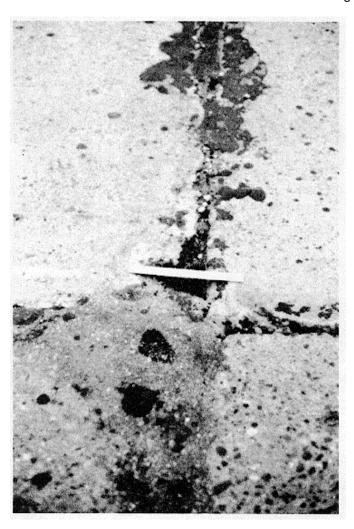

Figure B-132. Low-severity spalling, corner.

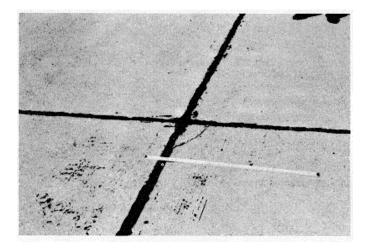

Figure B-133. Low-severity spalling, corner.

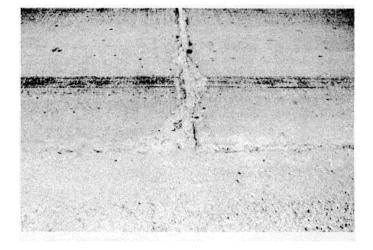

Figure B-134. Medium-severity spalling, corner.

Figure B-135. High-severity spalling, corner.

Name of Distress: Description:

Severity Levels:

If one or more corner spalls with the same severity level are in a slab, the slab is counted as one slab with corner spalling. If more than one severity level occurs, it is counted as one slab with the higher severity level.

Spalling, Joint.

Joint spalling is the breakdown of the slab edges within 2 feet of the joint.

A joint spall usually does not extend vertically through the slab, but intersects the joint at an angle. Spalling results from:

- 1. Excessive stresses at the joint caused by traffic loading or by infiltration of incompressible materials.
- 2. Weak concrete at the joint caused by overworking.
- 3. Water accumulation in the joint and freeze-thaw action.

Joint Spalling

			Length of spall	
Spall pieces	Width of spall			
		<2 feet	>2 feet	
Tight-cannot be easily removed (may be a few pieces	<4 inches	L	L	
missing)	>4 inches	L	L	
Loose-can be removed and some pieces are missing; if	<4 inches	L	M	
most or all pieces are missing, spall is shallow, less than	>4 inches	L	M	
1 inch.				
Missing-most or all pieces have been removed	<4 inches	L	M	
	>4 inches	M	Н	

See figures B-136 through B-138.

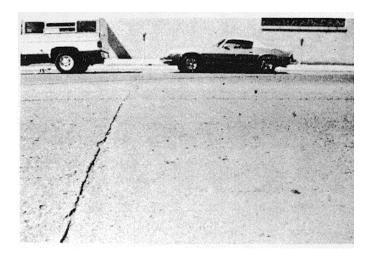

Figure B-136. Low-severity spalling, joint.

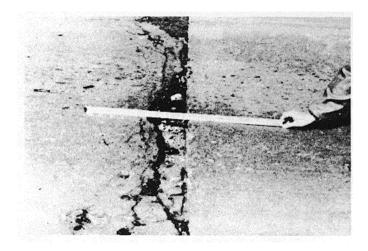

Figure B-138. High-severity spalling, joint.

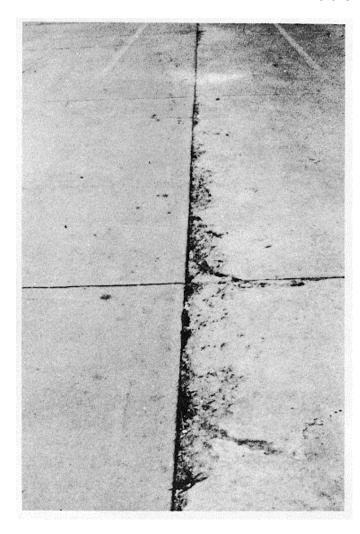

Figure B-137. Medium-severity spalling joint.

A frayed joint where the concrete has been worn away along the entire joint is rated as low severity.

If the joint is along the edge of one slab, it is counted as one slab with joint spalling. If spalling is on more than one edge of the same slab, the edge having the highest severity is counted and recorded as one slab. Joint spalling can also occur along the edges of two adjacent slabs. If this is the case, each slab is counted as having joint spalling.

How to Count:
